## 1 Introduction

### 1.1 Optimization problem

$$\min_{w \in \mathbb{R}^p} f(w) = L(w) + \lambda \Omega(w)$$

$$\min \sum_{i=1}^{N} \log \left( 1 + \exp(-y^{(i)} w^{T} x^{(i)}) \right) + \lambda ||w||^{2}$$
(1)

where  $i=\ldots,N$  are the dataset indices,  $y^i\in\{-1,1\}$  is the response variable corresponding to the negative or positive class,  $x^i\in\mathbb{R}^p$  are dataset examples.

$$\nabla f(w) = X^T r + 2\lambda w, \quad r = -y^{(i)} \sigma(-y^{(i)} w^T x^{(i)})$$

$$\nabla^2 f(w) = X^T D X + 2\lambda I, \quad d_{ii} = \sigma(y^{(i)} w^T x^{(i)}) \sigma(-y^{(i)} w^T x^{(i)})$$

**Proposition 1.** Problem (1) admits a unique optimal solution.

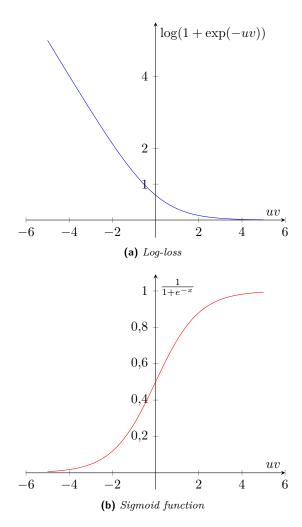

Figure 1: Log-loss and sigmoid function plots  $\,$ 

- $uv \gg 0$ : the example is labelled correctly
- $uv \ll 0$ : the class assigned to the example is the wrong one
- the hessian matrix is positive defined  $\forall w$ , this means that the objective function, which is quadratic, is coercive and for the continuity that function admits global minimum, so f(w) has finite inferior limit
- the hessian matrix being positive defined implies also that the objective function is strictly convex (on the other hand the loss function is just convex, due to its hessian matrix being positive semi-defined), this implies that if the global minimum exists, that solution is unique
- a global minimum is a point that satisfy  $\nabla f(w^*) = 0$ , which is a sufficient condition implied by the convexity of the problem, see figure 1a on the preceding page
- the  $\ell_2$  regularization implies that the objective function is strongly convex, this speeds up the convergence
- further more we can assume that  $\nabla f(w)$  is Lipschitz-continuous with constant L

## 2 Mini-batch gradient descent variants

#### 2.1 Fixed step-size

Mini-batch Gradient Descent with fixed or decreasing step-size

```
dati w^0 \in \mathbb{R}^n, f(w) = \sum_{i=1}^N f_i(w), k=0 e \{\alpha_k\} \mid \alpha_k = \alpha \vee \alpha_k = \frac{\alpha_0}{k+1} while (\|\nabla f(w^k)\| > \varepsilon) shuffle \{1,\ldots,N\} in N/M blocchi B_1,\ldots,B_{N/M} di dimensione 1 < |B_t| = M \ll N y_0 = w^k for t=1,\ldots,N/M get mini-batch indices from B_t y_t = y_{t-1} - \alpha_k \frac{1}{M} \sum_{j \in B_t} \nabla f_j(y_{t-1}) end for w^{k+1} = y_{N/M} k = k+1 fine epoca end while
```

#### 2.2 Stochastic line search

#### Mini-batch Gradient Descent with Armijo line search

```
dati w^0\in\mathbb{R}^n , f(w)=\sum_{i=1}^N f_i(w) , k=0 , \alpha_0>0,\,\gamma\in(0,1),\,\delta\in(0,1)
   _{2} while (\|\nabla f(w^{k})\|>arepsilon)
                  shuffle \{1,\ldots,N\} and split B_1,\ldots,B_{N/M} such that 1<|B_t|=M\ll N
   y_0 = w^k
   for t = 1, \dots, N/M
                        get mini-batch indices i_t from B_t
                          approximate true gradient 
abla f_{i_t}(w) = rac{1}{M} \sum_{j \in B_t} 
abla f_j(y_{t-1})
                          \alpha = \mathtt{reset}(), q = 0
                          while (f_{i_t}(y_{t-1} - \alpha \nabla f_{i_t}(w)) > f_{i_t}(y_{t-1}) - \gamma \alpha \|\nabla f_{i_t}(y_{t-1})\|^2)
                              \alpha = \delta \alpha
                              q = q + 1
11
                         end while
12
                     \alpha_t = \alpha
                    y_t = y_{t-1} - \alpha_t \nabla f_{i_t}(y_{t-1})
_{15} end for
